EXECUTIVE SUMMARY

Focus on $100–250 products, discount by at least 10% and bundle natural pairs, then test on real orders

32%

of minimum revenue comes from $100–250 products, which are 24% of the range

+35%

demand at 20–30% off compared with no discount, in the same category and at the same price

10.5×

how much more often keyboards and mice are packaged together than by chance

The question

Where should an electronics seller focus its prices, discounts and product bundles to sell more?

The evidence

42,675 raw listings cleaned into 8,149 products. With no order data available, sales are estimated from Amazon's "bought in past month" labels, as minimums.

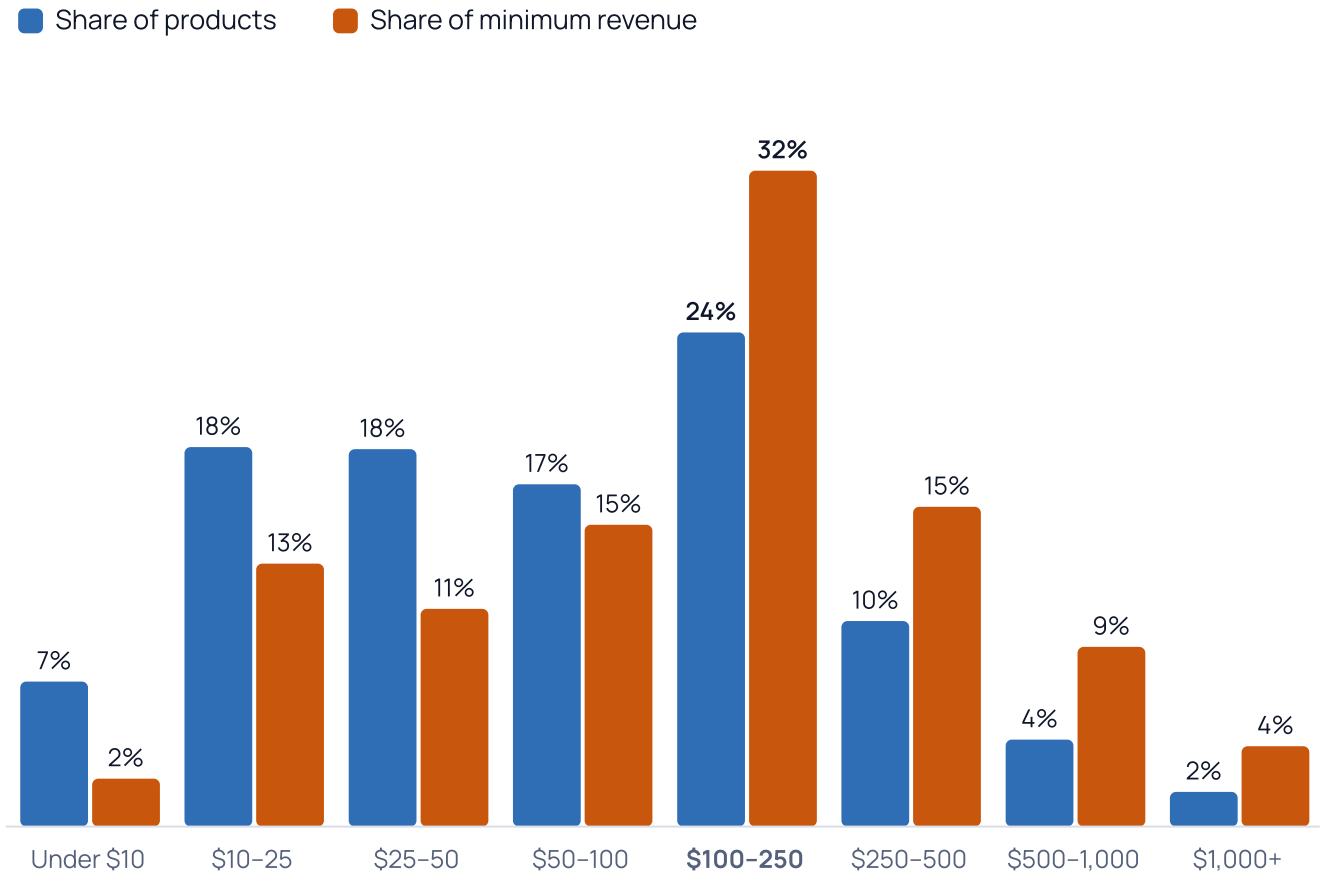

The answer

- Revenue and volume sit in different price ranges.
- Token discounts show no clear link to demand. Discounts of 10% or more do.
- The data shows links, not causes, so these are ideas to test rather than proof.

FINDING 1

Mid-priced products earn the most revenue, while the cheapest products bring volume but little revenue

Share of products and minimum revenue, by selling price

- **$100–250 leads.** It is 24% of the range and 32% of minimum revenue, the largest share of any price band.
- **Under $25 is a volume play.** It is 25% of the range and 58% of units, but only 15% of revenue.
- **Focus matters.** Printers and ink is the largest category at 17% of revenue, and the top 10% of products hold 68% of units.

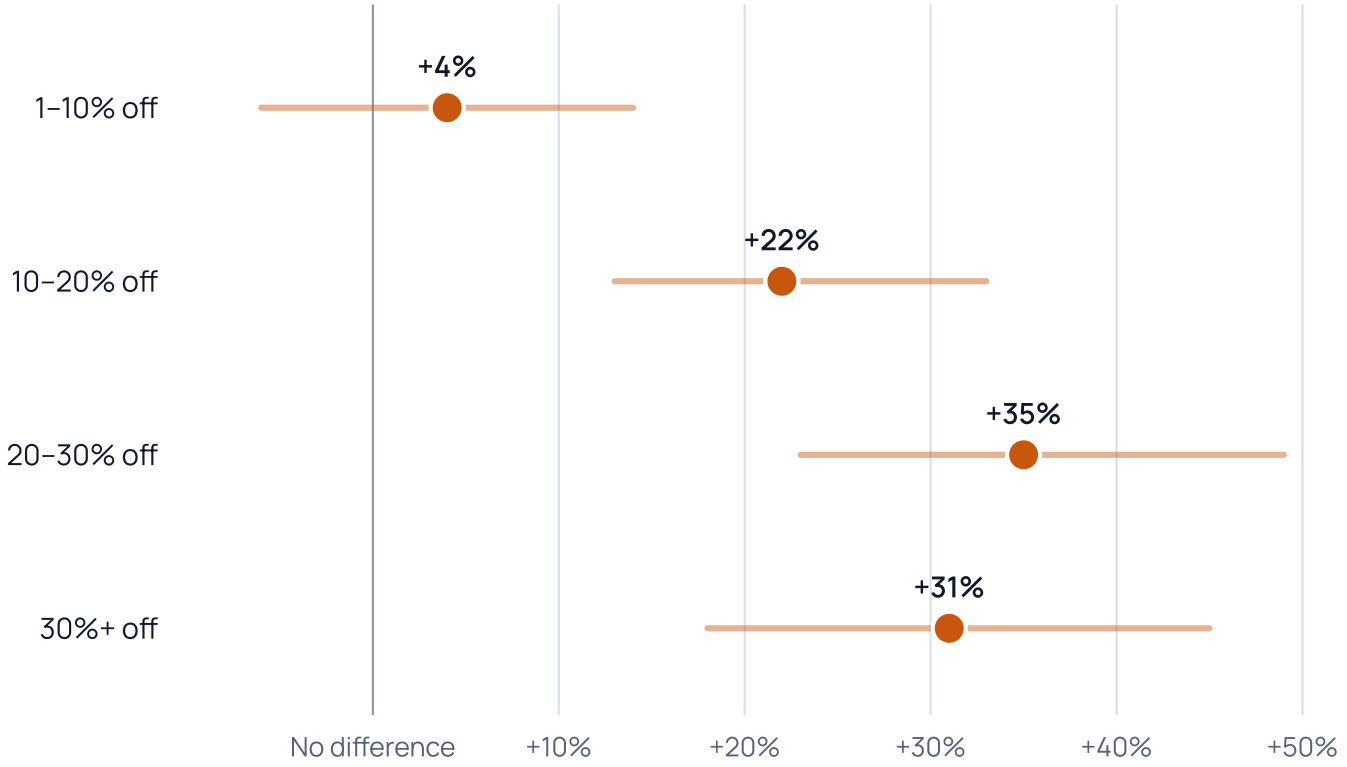

SO WHAT

Use cheap products to attract volume, but judge the range by what the $100–250 band earns.

FINDING 2

Discounts link to higher demand only from about 10%, and going past 30% shows no further gain

Demand against no discount, same category and selling price

Demand vs no discount. Dot: best estimate. Bar: 95% range.

- **Token discounts:** 1–10% off showed no clear difference.
- **The useful range:** demand was 22% higher at 10–20% off and 35% higher at 20–30% off.
- **A caution:** also allowing for review counts lowers the 35% to 25%, as better products may earn both sales and discounts.
- **No clear effect:** coupons and sponsored listings showed no reliable link with demand.

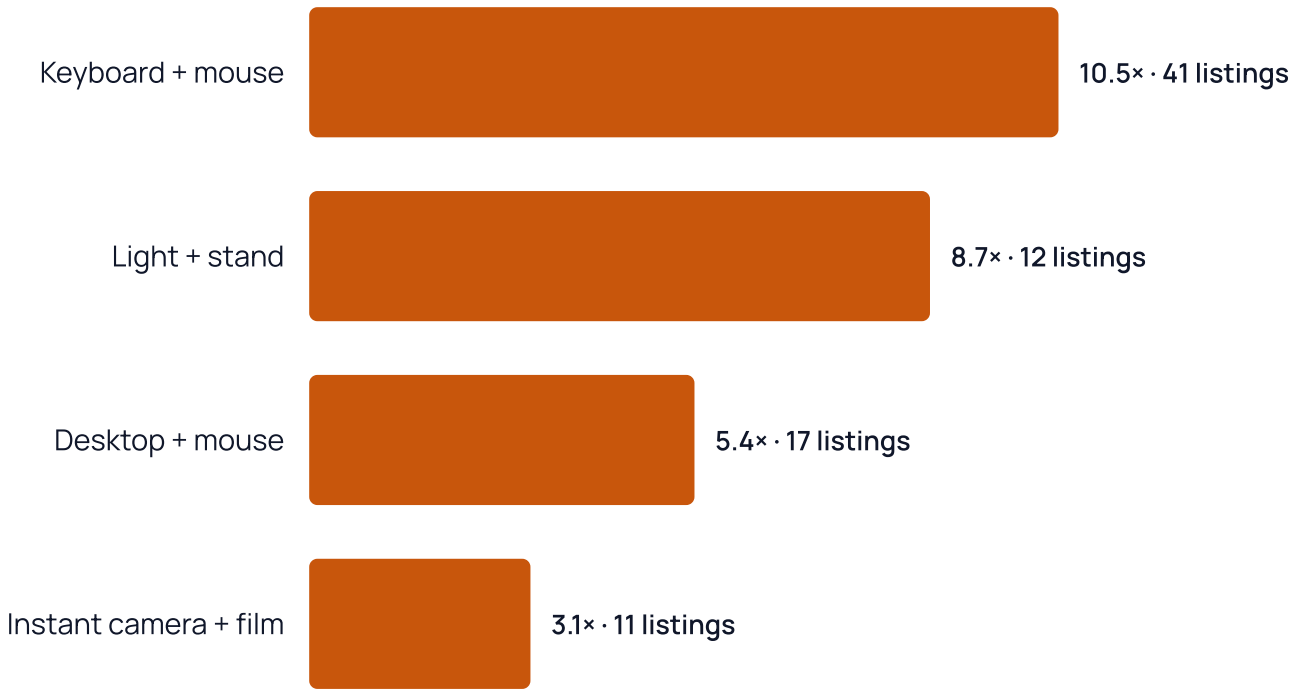

SO WHAT

Skip token discounts. Test 10–30% off first, as deeper cuts give up margin with no visible gain in demand.

FINDING 3

Four natural pairs are worth trying, though bundling has not yet been shown to lift demand

Pairs that sellers package together

How many times more often the pair appears together than by chance

- **Pairs that held up:** these four remained after checking the listing titles behind each one and removing pairs that were really features, such as a "case with stand".
- **Not yet proven:** listings sold as a pair showed 8% lower demand overall, a difference that was not statistically reliable.
- **What this measures:** what sellers package together, not what shoppers buy together, as the data has no orders.

SO WHAT

Treat these pairs as candidates. Only real order data can show whether customers want them.

RECOMMENDATION

Three moves to trial on real orders before rolling them out

What to do

1. **Prioritise the $100–250 range**
   Review stock and promotion there first, as this band earns the largest share of revenue.
2. **Replace token discounts**
   Test 10–20% and 20–30% off against no discount, and hold off on going past 30%.
3. **Pilot natural pairs**
   Start with keyboard and mouse, and desktop and mouse.

Next step

Use the seller's own order data for a true basket analysis, and run controlled tests to measure what discounts actually cause.

Limits to keep in mind

- **Links, not causes.** Better products may earn both discounts and sales.
- **A short window.** The data covers 10 days, so it cannot show seasonal or long-term patterns.
- **Estimated sales.** Demand and revenue are minimums from rounded labels, not actual sales.
- **Imperfect categories.** Products were sorted from their titles. A hand check of 100 found 83 right, 9 wrong and 8 left in "Other".
- **Not yet tried.** None of this has been tested with a real seller.
